#### Matrix Chain Products (MCP)

- Review: Matrix Multiplication.
  - C = A \*B
  - $A ext{ is } p \times q ext{ and } B ext{ is } q \times r$

$$C[i,j] = \sum_{k=0}^{q-1} A[i,k] * B[k,j]$$

• O(pqr) time

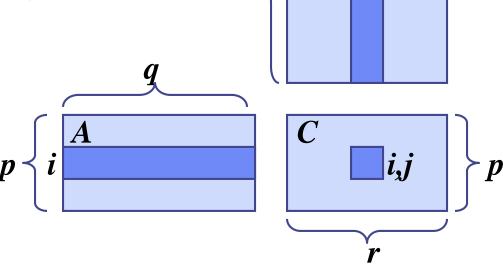

```
for (i=0; i<p; i++)

for (j=0; j<r; j++){

c[i,j]=0;

for (k=0; k<q; k++)

c[i,j]+=a[i,k]*b[k,j];
}
```

B

#### **Matrix Chain-Products**

- Problem definition
  - Given n matrices  $A_0$ ,  $A_1$ , ...,  $A_{n-1}$ , where  $A_i$  is of dimension  $d_i \times d_{i+1}$
  - How to parenthesize A<sub>0</sub>\*A<sub>1</sub>\*...\*A<sub>n-1</sub> to minimize the overall cost?

#### Example of MCP

The product A (2×3), B (3×5), C (5×2), D (2×4) can be fully parenthesized in 5 distinct ways:

```
(A (B (C D))) \rightarrow 5 \times 2 \times 4 + 3 \times 5 \times 4 + 2 \times 3 \times 4 = 124

(A ((B C) D)) \rightarrow 3 \times 5 \times 2 + 3 \times 2 \times 4 + 2 \times 3 \times 4 = 78

((A B) (C D)) \rightarrow 2 \times 3 \times 5 + 5 \times 2 \times 4 + 2 \times 5 \times 4 = 110

((A B C) D) \rightarrow 3 \times 5 \times 2 + 2 \times 3 \times 2 + 2 \times 2 \times 4 = 58

(((A B) C) D) \rightarrow 2 \times 3 \times 5 + 2 \times 5 \times 2 + 2 \times 2 \times 4 = 66
```

The way the chain is parenthesized can have a dramatic impact on the cost of evaluating the product.

## An Enumeration Approach

#### Matrix Chain Product Alg.:

■ Try all possible ways to parenthesize  $A=A_0*A_1*...*A_{n-1}$ 

Pick the one that is best

#### Running time:

- The number of ways of parenthesizations is equal to the number of binary trees with n leave nodes
- It is called the Catalan number, and it is almost 4<sup>n</sup>

$$C_n = \frac{1}{n+1} \binom{2n}{n}$$

 $((A_0(A_1A_2))A_3)$  binary tree

## Observations Leading to DP

- Define subproblems:
  - Find the best parenthesization of A<sub>i</sub>\*A<sub>i+1</sub>\*...\*A<sub>j</sub>.
  - Let N<sub>i,j</sub> denote the minimum number of operations required by this subproblem.
  - The optimal solution for the whole problem is  $N_{0,n-1}$ .
- Subproblem optimality: The optimal solution can be defined in terms of optimal subproblems
  - There has to be a final multiplication (root of the expression tree) for the optimal solution.
  - Say, the final multiply is at index i:  $(A_0^*...*A_i)*(A_{i+1}^*...*A_{n-1})$ .
  - Then the optimal solution  $N_{0,n-1}$  is the sum of two optimal subproblems,  $N_{0,i}$  and  $N_{i+1,n-1}$  plus the time for the last multiply.

## Three-Step DP Formula

- To solve matrix chain-product with DP
  - Optimum-value function
    - N<sub>i,i</sub>: the minimum number of operations required by parenthesizing A<sub>i</sub>\*A<sub>i+1</sub>\*...\*A<sub>i</sub>.
  - Recurrent equation

$$N_{i,j} = \min_{i \le k < j} \{ N_{i,k} + N_{k+1,j} + d_i d_{k+1} d_{j+1} \}$$

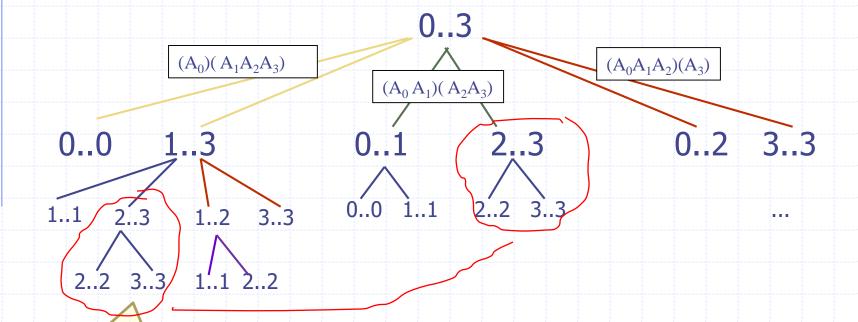

with  $N_{i,i} = 0, \forall i$ 

# $(A_{i+1} * A_{i+1} * A_{k})(A_{k+1} * A_{k+2} * ... * A_{j})$ $d_{i} \times d_{k+1} \qquad d_{k+1} \times d_{j+1}$

- Answer
  - N<sub>0, n-1</sub>

$$|d_{k+1} \times d_{j+1}|$$

## Subproblem Overlap

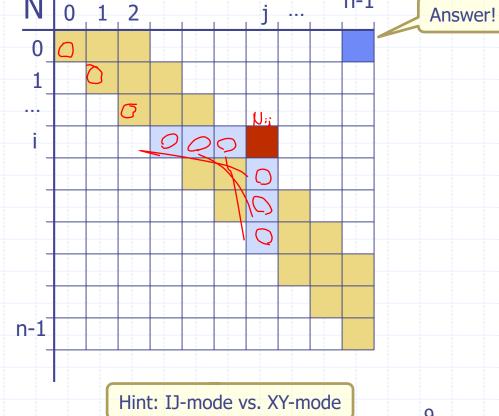

Due to the overlap, we need to keep track of previous results

## Table Filling for DP

- The bottom-up approach fills in the upper-triangle of the nxn array by diagonals, starting from N<sub>i,i</sub>'s.
- N<sub>i,i</sub> gets values from pervious entries in row i and column j.
- Filling in each entry in the N table takes O(n) time  $\rightarrow$ Total time O(n<sup>3</sup>)
- Actual parenthesization can be found by storing the best "k" for each entry

Easy for back tracking

$$N_{i,j} = \min_{i \le k < j} \{ N_{i,k} + N_{k+1,j} + d_i d_{k+1} d_{j+1} \}$$

## Walkthrough of an MCP Example

Quiz!

Product of A<sub>0</sub> (2×3), A<sub>1</sub> (3×5), A<sub>2</sub> (5×2), A<sub>3</sub> (2×4)

$$N_{i,j} = \min_{i \le k < j} \{ N_{i,k} + N_{k+1,j} + d_i d_{k+1} d_{j+1} \}$$

$$N_{0,2} = \min \begin{cases} N_{0,0} + N_{1,2} + 2 \times 3 \times 2 \\ N_{0,1} + N_{2,2} + 2 \times 5 \times 2 \end{cases} = \min \begin{cases} 0 + 30 + 12 \\ 30 + 0 + 20 \end{cases} = 42$$

$$N_{1,3} = \min \left\{ \frac{N_{1,1} + N_{2,3} + 3 \times 5 \times 4}{N_{1,2} + N_{3,3} + 3 \times 2 \times 4} \right\} = \min \left\{ \frac{0 + 40 + 60}{30 + 0 + 24} \right\} = 54$$

$$N_{0,3} = \min \begin{cases} N_{0,0} + N_{1,3} + 2 \times 3 \times 4 \\ N_{0,1} + N_{2,3} + 2 \times 5 \times 4 \\ N_{0,2} + N_{3,3} + 2 \times 2 \times 4 \end{cases} = \min \begin{cases} 0 + 54 + 24 \\ 30 + 40 + 40 \\ 42 + 0 + 16 \end{cases} = 58$$

Optimum value of k (for back tracking)

Solution (after back tracking) 
$$\rightarrow$$
  $(A_0A_1A_2)(A_3)=(A_0(A_1A_2))(A_3)$ 

#### **Exercise**

Quiz!

• Product of  $A_0$  (2×3),  $A_1$  (3×5),  $A_2$  (5×2),  $A_3$  (2×4),  $A_4$  (4×1)

A <sub>0</sub> 2×3	A <sub>1</sub> 3×5	A <sub>2</sub> 5×2	A <sub>3</sub> 2×4	A <sub>4</sub> 4×1
0 ► 2×3	30 2×5	42 C	-58 2×4 \	2×1

A <sub>0</sub> 2x3	2×3	2×5 k=0	2×2 k=0	2×4 k=2	2×1 k=
A <sub>1</sub> 3×5		<b>0</b> 3×5∠	30 3×2 k=1	54 3×4 k=2	3×1 k=
A <sub>2</sub> 5×2			0 v 5×2	40 5×4 k=2	5×1 k=
				_	

2×4		2×4	2×1 k=3
A <sub>4</sub>			<b>0</b>

$$N_{i,j} = \min_{i \le k < j} \{ N_{i,k} + N_{k+1,j} + d_i d_{k+1} d_{j+1} \}$$
